Arkiv pitch: 3-minute script

Track: **Build on Arkiv (from scratch)** · deck: `docs/pitch/arkiv-deck.html` (press **p** to present, arrows to move) · ~400 words at a calm pace.

The 15-second hook (say it first, word for word):
"Semmal is a marketplace where robots hire AI agents. Every booking, quote, hire, job and score is an Arkiv entity, owned by whoever is accountable for it, including the robot's own wallet. So you can check a robot's record without trusting us."

Minute by minute

Time	Slide	Say	Show / point at
0:00–0:15	1 · Hook	The hook above.	The headline and the four fact pills.
0:15–0:35	2 · The problem	"Four parties: customers, robot owners, the robots themselves and agent developers. In a normal database the operator could delete a failed job or edit a score. So the record has to belong to its author."	The four cards.
0:35–1:00	3 · Entities	"Every coordination step is an entity: robot and agent profiles, bookings, the robot's quotes, its job claims for the agents it hires, its episodes and incidents, and reputation checkpoints. We index only what we filter on: wallet, robot, task, kind, trust mode, price, and the job score."	The owner column: robot's own wallet in orange.
1:00–1:25	4 · Ownership	"The robot has its own key, made on the robot PC, never sent anywhere. It can write only its four evidence schemas under a fee cap. Every reader checks that owner, creator and the wallet inside match, and that it's the wallet on the robot's profile. People sign in their own wallet; there is no platform key."	The three-step flow.
1:25–1:45	5 · Expiry	"Expiry does our coordination: bookings, quotes and job claims expire at their own deadline. Registrations lapse after 90 days unless renewed; evidence and scores live 120."	The three numbers.
1:45–2:15	6 · Scores	"After each job the robot scores itself, part by part, and writes the score as an indexed column. A robot's reputation is the mean of its job scores on Arkiv; an agent's comes from the scores the hiring robots signed. That ranks robots when you book and agents when a robot hires. Anyone can recompute it with one query, no key needed."	The query output: task_score 100, the parts.

2:15–2:35	7 · Screens	"Every feature reads Arkiv: the booking map, the agent market, your orders, owner requests, the evidence log, and 'What went to Arkiv', which reads a job's entity back with the score maths. Live now: 2 robots, 2 agents, 5 bookings, 7 episodes, 21 incidents."	The six cards and the live numbers.
2:35–2:50	8 · Deliverables	"Everything the track asks for is in the repo: schema.md, friction with 9 real issues, reach, why Arkiv, how we use it, writer wallets and a query in the README, MIT licence."	The checklist.
2:50–3:00	9 · Close	"Swap Arkiv for Postgres and users lose a robot record they don't have to trust us for. That's Semmal."	Team and links.

Deliverables to point at (Arkiv track)

Requirement	Where
Writes to Arkiv's testnet with the SDK; a user-visible feature reads it	8 schemas on Rabdi; booking map, agent market, orders, evidence, "What went to Arkiv"
README: writer wallet addresses + one query	README → "ETHGlobal Mumbai submission"; `pnpm arkiv:query`
/arkiv/schema.md and /arkiv/friction.md	`arkiv/schema.md`, `arkiv/friction.md`
One file per criterion	`arkiv/reach.md`, `arkiv/why-arkiv.md`, `arkiv/how-you-use-arkiv.md`
Public repo, open-source licence, AI use stated	github.com/jonathanvineet/semmal · MIT · README "How AI was used"

Likely questions

- **Why not a contract?** We need queryable records with owners and lifetimes, not logic; Arkiv gives us filters and expiry; payments are plain 0G transfers.
- **Can a robot lie?** Arkiv proves who wrote what and when, not that a sensor was right. The robot's identity is a signed challenge from its own key at registration.
- **What's off Arkiv?** Live position, exact addresses, camera frames, sessions, keys (see why-arkiv.md).
